Figure 1: NAMOSIM

Summary

NAMOSIM is a mobile robot motion planner designed for the problem of Navigation Among Movable Obstacles (NAMO). The planner simulates robots navigating in 2D polygonal environments where certain obstacles can be grasped and relocated to enable robots to reach their goals. NAMOSIM extends the classic navigation problem with a layer of interactivity, posing interesting research questions while remaining well-defined and amenable to both classical and learning-based approaches. NAMOSIM supports multi-robot environments and provides a baseline NAMO algorithm along with a communication-free coordination strategy. The simulator includes support for holonomic and differential-drive motion models and integrates with ROS2 for visualization in RViz.

NAMOSIM uses a modular agent-based architecture and includes a baseline NAMO algorithm (Stilman & Kuffner, 2005) implemented in the Stilman2005 agent, which also incorporates a communication-free coordination strategy for multi-robot scenarios. A variety of other agent types are implemented, and new agents utilizing alternative approaches can be created and integrated into the planner by implementing the **Agent** base class. Thus, new navigation algorithms, including those based on machine learning or AI, can be developed within NAMOSIM,

22 facilitating reproducible research on NAMO problems.

23 NAMOSIM is packaged as a ROS2 package for easy integration into robotics projects but
24 can also be used as a standalone Python module. It utilizes ROS2 messages for visualization
25 of environments and plans via RViz and includes several prebuilt scenarios for testing and
26 benchmarking. Scenarios are stored as SVG files, allowing custom scenarios to be created using
27 a free SVG editor such as Inkscape. NAMOSIM is intended for researchers and developers
28 working on robot navigation in dynamic environments, particularly where physical interaction
29 is necessary.

30 Statement of Need

31 Many applications in autonomous mobile robotics involve physical interaction with the envi-
32 ronment and social coordination with other agents. However, standard navigation planners
33 assume static, non-interactive environments, limiting their applicability in complex real-world
34 scenarios. NAMO problems involve not only path planning but also reasoning about which
35 obstacles to move, where to move them, and how to combine standard navigation with obstacle
36 manipulation. NAMOSIM addresses this gap by offering a simulation environment explicitly
37 designed to study and prototype NAMO algorithms. Additionally, NAMOSIM supports multi-
38 robot environments, facilitating reproducible research in multi-robot navigation among movable
39 obstacles (MR-NAMO).

40 Major Features

41 NAMOSIM provides a robust set of features to support research and development in Navigation
42 Among Movable Obstacles (NAMO):

- 43 ■ **Modular Agent-Based Architecture:** The simulator is built around a flexible Agent
44 interface, allowing users to implement and test custom NAMO planning algorithms. A
45 baseline implementation of the Stilman2005 planner is included for immediate use and
46 benchmarking.
- 47 ■ **Support for Multiple Robot Models:** NAMOSIM supports both holonomic and differential-
48 drive robot models, enabling realistic simulation of various robotic platforms.
- 49 ■ **ROS2 Integration:** NAMOSIM forms a ROS2 package, enabling seamless integration
50 into simulated and physical robotics projects and visualization via RViz.
- 51 ■ **2D Environment Simulation:** The simulator provides a customizable 2D environment
52 where users can define static and movable obstacles, supporting complex scenarios for
53 testing multi-robot coordination strategies and NAMO algorithms.
- 54 ■ **Prebuilt Scenarios and Tests:** NAMOSIM includes several custom scenario files for
55 benchmarking and testing of specific situations.
- 56 ■ **Multi-Robot Coordination:** The simulator supports multi-robot scenarios, and our
57 baseline agent Stillman2005 agent' implements the communication-free coordination
58 strategy presented in our IROS-2024 publication(Renault et al., 2024).

59 These features make NAMOSIM a versatile tool for prototyping, evaluating, and deploying
60 NAMO algorithms in diverse robotic applications.

61 Customizable Scenarios

62 NAMOSIM environments, or **scenarios**, are stored in SVG format and can be edited using any
63 SVG editor, such as Inkscape. The scenario SVG file contains the following key elements:

- 64 ■ The geometry of the static map
- 65 ■ The polygons and orientations of all robots and movable obstacles
- 66 ■ Configuration settings that define the behavior of the environment and robots

67 The static map can also be included as an image layer within the SVG to conveniently
68 incorporate ROS grid-map images generated by standard mapping tools.

69 Architecture

70 At a high level, NAMOSIM executes a SENSE-THINK-ACT loop that performs the following
71 functions at each iteration:

- 72 1. **SENSE**: Each agent senses the environment and updates its internal representation.
- 73 2. **THINK**: Each agent computes a new plan or updates its current plan.
- 74 3. **ACT**: Each agent selects a single discrete action to execute.

75 The loop is expected to execute at a regular frequency, with the assumption that all agent
76 functions run sequentially in a synchronized manner.

77 Stilman's Algorithm

78 NAMOSIM includes a baseline implementation of Stilman's 2005 NAMO algorithm ([Stilman
79 & Kuffner, 2005](#)). The key idea of this algorithm is to move obstacles to merge disjoint
80 components of the robot's free configuration space. The map is divided into a set of disjoint
81 **connected components**, where each cell in a given component is reachable from all other cells
82 in the same component. It can be proven that components are separated by movable obstacles
83 or are otherwise unreachable. The algorithm functions by moving obstacles to join components
84 until the robot's current component includes the goal cell.

85 The algorithm works by recursively performing the following two stages:

- 86 1. **SELECT_OBSTACLE_AND_COMPONENT**: The first stage performs a simplified
87 A* grid search, allowing the agent to pass through movable obstacles. It returns the ID
88 of the first movable obstacle encountered on the optimal path to the goal and the ID of
89 the component encountered after passing through the obstacle.
- 90 2. **OBSTACLE_MANIPULATION_SEARCH**: The second stage finds a **transit path**
91 from the robot's current position to a grasp pose near the obstacle. Then, it finds a
92 **transfer path** by performing an obstacle manipulation search to join the robot's current
93 component to the component selected in stage 1. If this stage fails, the obstacle and
94 component pair are added to an avoid-list, and the algorithm returns to stage 1.

95 Each iteration of the algorithm continues with a copy of the environment where the robot and
96 obstacle start from the poses resulting from the previous obstacle manipulation search. This
97 algorithm is explained in greater detail in Renault's 2023 PhD thesis ([Renault, 2023](#)).

98 Collision Detection

99 Custom agents can implement their own collision detection routines; however, the baseline
100 Stilman2005 agent detects collisions using a simple binary-occupancy grid during transit paths
101 (when not carrying an obstacle), assuming a circular robot footprint. When transporting a
102 movable obstacle, the robot footprint is non-circular, and collision detection is based on the
103 **convex swept volume** resulting from the area swept by the combined robot-obstacle footprint
104 due to the action motion. Although computationally expensive, this ensures all possible
105 collisions are detected, regardless of the shape of the robot or obstacle.

106 Social Costmap

107 A novel contribution in the baseline implementation is the option to use a social costmap
108 during the obstacle manipulation search to guide obstacle placement decisions. This allows
109 robots to place obstacles in areas less likely to block the free passage of other agents, including
110 humans, reducing the likelihood that obstacles will need to be moved again. The key heuristic

of the social costmap is to **avoid narrow corridors and central areas**, assigning higher costs to narrow corridors and the centers of open spaces. This helps robots avoid placing obstacles in front of doorways or in the center of rooms. The social costmap is explained in greater detail in Renault (2023).

Conflict Avoidance and Deadlock Resolution

The baseline Stilman2005 agent can avoid conflicts and resolve deadlocks with other agents. Conflict avoidance works by looking ahead along the agent's current plan for a fixed number of steps, called the **conflict horizon**. Within this horizon, the agent simulates each planned action and checks for potential conflicts, such as an obstacle moved by another robot or a collision with another robot crossing the planned path.

The Stilman2005 agent avoids conflicts by either pausing or replanning around them. A deadlock is detected when a conflict configuration is repeatedly encountered, even after replanning. To resolve deadlocks, the agent follows an evasion strategy as described in (Renault et al., 2024).

Acknowledgements

This research was supported by an Inria ADT initiative. We express our gratitude to Benoit Renault, whose PhD thesis forms the foundation of this work.
